# **NCI Imaging and Informatics Community Webinar**

#### **NEWS**

Starting in Fall 2023, the monthly NCI Imaging Informatics Webinar will be organized by the Cancer Imaging Program (CIP).

Information about upcoming webinars can now be found at https://imaging.cancer.gov/imaging\_webinar/default.htm

Information about upcoming webinars will also be distributed via the Google group.

This wiki page will continue to provide slides and recordings for all webinars between 2012 and April 2023.

Date	Agenda	Recording
10 Apr	Al in Cardiovascular Imaging	Recording
2023	Dr. Tim Leiner (Mayo Clinic)	Transcript
	Machine learning and especially deep learning hold great promise to improve patient care. In several domains, algorithms perform as good as or better than fellowship trained radiologists for identification of abnormalities in clinically acquired images. However, there are much broader applications beyond image analysis such as patient selection and examination scheduling, image acquisition and reconstruction, using image data for prognostic purposes, and combing image data with information from electronic health records, laboratory and genetic data. Furthermore, in order for algorithms to be broadly accepted, there are many scenarios where it is important for the clinician that results are explainable. In addition, clinical deployment and workflow should be taken into consideration when designing the algorithm and bringing it to clinical practice. In my lecture I will focus on these aspects from a cardiovascular imaging perspective.	

06 Mar	ChatGPT and the potential healthcare implications of large language models	Recording
2023	George Shih, MD, Weill Cornell Medicine	Transcript
	ChatGPT has exploded into our world and it has the potential to be a widely available near omniscient AI, including many applications in healthcare for providers, patients, researchers, educators, students, and healthcare companies. In this talk, we'll explore examples of ChatGPT in healthcare, and discuss the potential impact and implications to stakeholders as ChatGPT evolves and improves over time.	
6 eb 023	Radiation Dose Reduction in CT and its Effects on Quantitative Imaging and Machine Learning/Artificial Intelligence Algorithms	Recording
023	Dr. Michael McNitt-Gray, UCLA	Transcript
	CT is widely used in clinical practice with applications ranging from early detection (screening), characterization (diagnosis) and assessment of response to therapy. There has been widespread concern over the radiation dose associated with these scans, especially on pediatric patients or patients who get frequent scans. There have been significant developments which allow the reduction of radiation dose from CT including developments in automatic exposure control, advanced image reconstruction techniques, more efficient detector technologies among others that promise significant radiation dose reductions to patients, while maintaining clinical image quality. While these technologies are exquisite and should be investigated wherever possible in a clinical environment, their effects on quantitative measures extracted from CT images and machine learning algorithms have not been well characterized. These technologies may affect image quality in ways that may limit the generalizability of quantitative imaging and Artificial Intelligence/Machine Learning (Al/ML) methods. For example, advanced image reconstruction methods may be able to mitigate the increase in noise that is incurred when radiation dose is reduced, but there may be some impact on image resolution. In addition, many of these techniques are non-linear and adaptive to the local image anatomy and pathology, their impacts may be difficult to predict from application to application and even patient to patient (and yes, even within a patient). This presentation will provide examples of these effects and discuss possible methods to mitigate these effects, which hopefully will enable more generalizable deployment of quantitative imaging methods and Al/ML algorithms.	
5 Dec	Report of the MIDI Task Group about best practices and recommendations for medical imaging de-identification	Recording

7 Nov	Bringing AI from Hype to Reality for Routine Clinical Practice: Defining and Addressing the Gaps	MP4 file
022	Dr. Eliot Siegel, University of Maryland	Transcript
	Despite the ever-increasing number of publicly available imaging databases and oncology Al/Radiomics applications that have been curated and developed over the past more than 15 years, an extraordinarily small number of Al applications are available and in use for routine clinical cancer care by radiologists, oncologists, and other healthcare providers. This is the case despite large and carefully and expertly curated and annotated databases which have been generously funded and made available by NCI and other organizations.	Slides
	Mammography CAD/AI has a particularly interesting and unique history and adoption curve and while it is in widespread use throughout the US, there continues to be a large gap in accuracy between the small percentage of studies interpreted by subspecialist mammographers and the vast majority of studies interpreted by general radiologists. This presentation will discuss some of the reasons for this continuing gap and lack of adoption of mammograph CAD into clinical decision making.	
	Additionally, a combination of regulatory challenges, the lack of a paradigm for training on datasets consisting of both prior and follow-up studies, brittleness of algorithms that are not adaptive, bias due in part to lack of transparency of databases used to develop AI apps, lack of standards for consumption of on prem and off prem algorithms, multiple platforms for packaging and using applications and lack of post-market surveillance, questions about whom the algorithms should be designed for, and many other factors have hampered widespread adoption. This presentation will discuss some solutions to these challenges that could accelerate adoption of these algorithms which could substantially enhance care for oncology patients.	

03	NCI's Imaging Data Commons: Fall 2022 Update	MP4 file
Oct 2022	Andrey Fedorov, Ph.D., Harvard	Transcript
	The NCI's Imaging Data Commons (IDC) is a cloud-based repository of publicly available cancer imaging data colocated with the analysis and exploration tools and resources. IDC is a node within the broader NCI Cancer Research Data Commons (CRDC) infrastructure that provides secure access to a large, comprehensive, and expanding collection of cancer research data. In this presentation we will cover the highlights of IDC development that took place since the production release of the repository. Among other updates, we will discuss the new datasets that have been released by IDC, new features of the platform, and the ongoing work on expanding the learning materials, including the application of IDC and cloud computing to support reproducible AI research.  A cloud-based platform for the dissemination of deep learning models	Transcript
	Hugo Aerts, Ph.D., Harvard MGB	
	Recent advances in artificial intelligence in medicine have led to a profusion of studies that apply deep learning to problems in radiology and pathology, among others. However, the effective dissemination of deep learning algorithms remains challenging, inhibiting reproducibility and benchmarking studies, impeding further validation, and ultimately hindering their effectiveness in the cumulative scientific progress. In this talk, we will discuss a platform we are developing for the structured dissemination of deep learning models that is domain-, data-, and framework-agnostic, and can cater to different workflows and contributors' preferences. Ultimately, these efforts will bring much-needed transparency to AI and accelerate scientific discoveries, academic training, and clinical adoption of AI applications in medicine.	
)6 Jun	Bridging the gap between prostate radiology and pathology through machine learning	MP4 file
2022	Mirabela Rusu, PhD, Stanford University	Transcript
	The subtle difference in MRI appearance of prostate cancer and benign prostate tissue renders the interpretation of prostate MRI challenging, causing many false positives, false negatives, and wide variations in interpretation. My laboratory focuses on improving the interpretation of prostate MRI by developing deep learning models that automatically localize indolent and aggressive prostate cancers on MRI scans. The novelty of our methods comes from using whole-mount pathology images to label MRI images and to create pathomic MRI biomarkers of aggressive and indolent cancers. Our approach achieved an area under the receiver operator characteristics curve of 0.93 evaluated on a per-lesion basis and outperformed existing deep learning models. In patients outside our training cohorts, such predictive models will outline the extent of cancer on radiology images in the absence of pathology images, thus helping guide the prostate biopsy and local treatment.	
	The talk will focus on discussing recent contributions from my lab on registering whole-mount pathology images with MRI, training deep learning models to extract pathomic MRI biomarkers and using them in training deep learning models to detect and distinguish indolent and aggressive prostate cancers on MRI, and showing the benefits of using labels from pathology in training deep learning models to distinguish indolent from aggressive prostate cancer on MRI.	
4 Apr	Machine Intelligence/Data Science in Medical Imaging of Breast Cancer and COVID-19	MP4 file
2022	Maryellen Giger, Ph.D, University of Chicago  Artificial Intelligence in medical imaging involves research in task-based discovery, predictive modeling, and robust clinical translation. Quantitative radiomic analyses, an extension of computer-aided detection (CADe) and computer-aided diagnosis (CADx) methods, are yielding novel image-based tumor characteristics, i.e., signatures that may ultimately contribute to the design of patient-specific cancer diagnostics and treatments. Beyond human-engineered features, deep convolutional neural networks (CNN) are being investigated in the diagnosis of disease on radiography, ultrasound, and MRI. The method of extracting characteristic radiomic features of a lesion and/or background can be referred to as "virtual biopsies". Various AI methods are evolving as aids to radiologists as a second reader or a concurrent reader, or as a primary autonomous reader. In addition, performance evaluations, as well as considerations of robustness and repeatability, are necessary to enable translation. This presentation will discuss the development, validation, database needs, and ultimate future implementation of AI in the clinical radiology workflow including examples from breast cancer and COVID-19. In addition, aspects of MIDRC (midrc.org) will be discussed.	Transcript
)7 //or	Al/ML Trends in Oncology and the Rugged Path Towards the Clinic	MP4 file
Mar 2022	Artificial intelligence (AI) and Machine learning (ML) algorithms are currently transforming biomedical research, especially in the context of cancer research and clinical care. Despite the tremendous potentials in automating workflow, personalizing care, and reducing health disparity, to name a few prospects, their application in oncology and healthcare has been limited in scope with less than 5% of major healthcare providers implementing any form of AI /ML solutions. This can be attributed to multitude of concerning issues regarding the deployment of AI/ML driven technologies into the clinic. These concerns include but not limited to skepticism related to commercialization hype, under representative training data, inherent implementation bias, lack of robustness and absence of prediction transparency. In this work, we will discuss some of these impending challenges and highlight different approaches for detecting and mitigating such bias in implementing clinical AI/ML algorithms. We further show examples of applying these approaches in oncology applications from our work and others and discuss their implications to pave the way for AI/ML in clinical practice.	Transcript

Thomas Yankeelov, PhD, University of Texas Austin  Our lab is focused on integrating quantitative imaging data with mechanism-based, mathematical models to predict treatment response. In this presentation, we will discuss some of our preliminary efforts at building digital twins to achieve this goal. We will begin by considering the I-SPY trials for breast cancer as a specific example of how the success of adaptive, population-based clinical trials indicate that digital twins can lead to the success of adaptive, indiv idual-based, clinical trials. Then we will emphasize the importance of physics and biology-based mathematical models for constructing digital twins. Finally, we will illustrate how these ideas are beginning to play out in predicting and optimizing neoadjuvant therapy for breast cancer.  Precision Medicine Approach to Breast Cancer Detection and Diagnosis  Martin Yaffe, PhD, Sunnybrook Research Institute and The University of Toronto	Transcript  MP4 file

Precision Medicine Approach to Breast Cancer Detection and Diagnosis	
Martin Yaffe, PhD, Sunnybrook Research Institute and The University of Toronto	Transarint
	Transcript (vtt)
Dr. Yaffe will describe a multi-platform approach under investigation in his lab to improve the effectiveness of breast cancer detection and diagnosis. We are developing radiomic tools to guide the stratification of women for breast cancer screening that will be more accurate and efficient in detection than the "one size fits all" use of mammography whose accuracy suffers, particularly in dense breasts. We employ microsimulation modeling to guide that work. We are also exploring the integration of radiomic information from in vivo medical images with histopathology, single-cell multiplex biomarker analysis, and targeted molecular sequencing to better characterize breast and other cancers and their immune environment and to explore their spatial heterogeneity. Octob	Multiplexed Tissue Imaging to Study Cancer	MP4 file
er 4, 2021	Sandro Santagata, MD PhD	Transcript
	Our team at the Harvard Medical School's Lab of Systems Pharmacology has generated reagents, workflows, and data analysis/visualization approaches for multiplexed tissue imaging. We developed tissue-based cyclic immunofluorescence (t-CyCIF) for subcellular imaging of formalin-fixed and paraffin-embedded (FFPE) and frozen tissues across 20-60 different proteins markers from a single tissue section. To support the use of multiplexed tissue imaging in the NCI Human Tumor Atlas Network (HTAN), we have developed algorithms and workflows to analyze these complex images, digital docents for their narrated viewing, and reporting standards for public data sharing. The information from these imaging methods complement data acquired by microregion spatial transcriptomics technologies. We have also used high-resolution imaging of tissues to identify functional interactions (e.g., immune synapses) in cancer tissues and have created multiplexed 3D cancer atlases to more completely characterize the architecture of the tumor-immune landscape in colon cancer and in melanomas, from pre-cancer lesions through metastasis.	
	Imaging Data Commons Production Release Update	
	Andrey Fedorov, PhD	
	The National Cancer Institute (NCI) Cancer Research DataCommons (CRDC) aims to establish a national cloud-based data science infrastructure. The goal of IDC is to enable a broad spectrum of cancer researchers, with and without imaging expertise, to easily access and explore the value of deidentified imaging data and to support integrated analyses with non-imaging data. We achieve this goal by co-locating versatile imaging collections with cloud-based computing resources and data exploration, visualization, and analysis tools. The IDC pilot was released in October 2020. In this presentation, we will give a brief overview of the capabilities of the production release of the IDC platform, and discuss the next steps for the development.	
June 7,	Medical Imaging De-Identification Initiative (MIDI)	MP4 file
2021	A DICOM dataset for evaluation of medical image de-identification	Transcript
	Dr. Fred Prior (UAMS)	
	A growing number of tools and procedures claim to properly de-identify image data. Based on our decade of experience managing the Cancer Imaging Archive (TCIA) on behalf of NCI, we developed a DICOM dataset that can be used to evaluate the performance of de-identification algorithms. DICOM objects were selected from datasets published in TCIA. Synthetic Protected Health Information (PHI) was generated and inserted into selected DICOM Attributes to mimic typical clinical imaging exams. The DICOM Standard and TCIA curation audit logs guided the insertion of synthetic PHI into standard and non-standard DICOM data elements. An answer key was created based on our knowledge of the placement of synthetic data and the DICOM standard's guidelines for what actions should be taken in regard to the synthetic PHI. A TCIA curation team tested the utility of the evaluation dataset and answer key.	
	Medical Image De-Identification using Cloud Services	
	Dina Mikdadi, Dr. Benjamin Kopchick	
	Patient privacy rules require the removal of Protected Health Information (PHI) before sharing images publicly. Manual de-identification is no longer scalable due to the rapid increase in imaging data volume. Our goal was to configure and test the efficacy of a cloud service for automated medical image de-identification (MIDI). One such service for DICOM images is Google Cloud Platform's Healthcare API. Training and test datasets for validation of image de-identification, specifically prepared by the placement of synthetic PHI in DICOM headers and image pixel data, were obtained from The Cancer Imaging Archive. The customized MIDI pipeline correctly performed 99.8% of expected actions on DICOM header data elements. For image pixel data, one false-positive case was noted, while all sensitive information was correctly removed from image pixel data. Throughput averaged at 58.4 images per second. This implementation of the MIDI pipeline holds promise for automated de-identification at scale. However, verification by a human expert is still currently recommended.	
May 3,	Establishing next generation dynamic susceptibility contrast MRI based biomarkers for neuro-oncologic applications	MP4 file
3, 2021	Dr. Chad Quarles, PhD	Transcript
	Dynamic susceptibility contrast (DSC) MRI is one of the most widely used physiologic imaging techniques in neuro- oncology, enabling the differentiation of glioma grades, identification of tumor components in non-enhancing glioma, reliable detection of recurrence, and early detection of therapy response. This presentation will highlight how an improved understanding of the biophysics of the contrast mechanisms underlying DSC-MRI enabled the recent standardization of acquisition protocols for multi-site clinical trials, is leading to the field's first benchmark for software validation, and is informing the development of advanced pulse sequences and analysis strategies tailored to specific clinical challenges faced in the management of brain cancer patients.

March 1,	Precision Surgery: Intraoperative molecular imaging to improve margin detection	MP4 file
1, 2021	Dr. Eben Rosenthal, Professor of Otolaryngology, Head & Neck Surgery and Radiology, Stanford University	Transcript
	Cancer is nearly always a surgically treated disease. Almost 80% of patients with early stage solid tumors undergo surgery at some point within their treatment course. A major gap in quality of care remains the high rate of tumorpositive margins in head and neck cancer (HNC) following surgical resections. Positive margin rates are directly correlated with lower survival but have remained unchanged at 25% for the last two decades! Primary factors that have impeded improving the rate of tumor-positive margins include subjective surgeon assessment as well as the limited amount of the tissue that can be sampled for intraoperative frozen-section analysis. We have demonstrated that use of intraoperative molecular imaging (IMI) can objectively identify the area on the tumor specimen most likely to contain a tumor-positive margin ("sentinel margin"). In a prospective evaluation, a fluorescently-labeled tumor-specific contrast agent is administered intravenously to the patient several days prior to surgery. After the surgical resection, the specimen is evaluated with IMI, in which near infrared imaging is used to identify the location of the sentinel margin on the surgical specimen. This evaluation is compared to subjective assessments of the deep tumor margin by palpation, considered the standard of care. It is expected that IMI imaging will be more accurate in identifying the sentinel margin, and will shorten the time to histological diagnosis while maintaining tissue orientation and high histological image quality. The translation of these new technologies has the potential to double the five-year survival rate of patients with HNC as well offer the potential to improve care for other cancer types as well.	
Febru ary 1,	Orchestration of distributed image archives Jonas Almeida and Praphulla Bhawsar	MP4 file
2021	Recent advances in the use of HTTP range requests to traverse bioformats*, coupled with a general move to "zero footprint" image informatics solutions, enable the creation of image archives as an exercise in governance. A particular feature of this configuration is that the images do not have to be copied or moved from their primary location. This has two interesting effects: a) the image owner remains in control of its governance, and b) training of Al classifiers can be federated across image sets that are not even shared.	Transcript
